

ICT & Infra S3 Automation & Orchestration, week 3

Class:	CB01
Student number:	4961854
Student name:	Heiko Morales

Introduction

This week you will practice creating Ansible Playbook(s) to automate a complex process. Before executing the assignment, ensure that you have working Ansible control node. For this assignment, you must be familiar with preparing Apache server and hosting Flask application on it. To repeat the necessary steps, you can read this simple tutorial, which explains Apache installation steps; creation of simple Flask application; hosting a Flask app on Apache:

<https://www.codementor.io/@abhishake/minimal-apache-configuration-for-deploying-a-flask-app-ubuntu-18-04-phu50a7ft>

Similar (probably the same) steps you will need to automate in this assignment.

Assignment 1. Create a Playbook to automate hosting of a simple Flask application

Difficulty: ★★★★★☆.

You already know how to create a simple Ansible Playbook. Now it is time to create a Playbook that can prepare newly installed Linux machine to host a website. Additionally, you should be able to host Flask application automatically. For this assignment, you must execute the following steps:

1. Using Amazon EC2 service, manually create and configure (free tier) Ubuntu instance to host a website.
2. Test SSH connection to the Virtual Machine.
3. Read the steps (from codementor.io tutorial) of Apache configuration and simple Flask app hosting.
4. Create a simple Flask app (my_flask_app.py) on your local machine.
5. Create a Playbook to **automate**:
 - a. apache2 service installation on the VM;
 - b. mod_wsgi module installation;
 - c. Flask installation;
 - d. Generate and upload "my_flask_app.wsgi" file using Jinja2 templating. HOW TO: [Template a file out to a remote server](#)
 - e. Generate and upload "ExampleFlask.conf" file using Jinja2 templating.
 - f. Check if newly created/uploaded website is accessible. HOW TO: [Interacts with webservice](#)
6. Manually test if the website is working.

Provide screenshots (evidence) for your solution. Always explain your evidence! As a prof, we expect at least:

- A screenshot of running EC2 Ubuntu instance;
- A screenshot of successful SSH connection to the VM;
- Ansible Playbook file(s) that automates configuration of the VM.
- A proof that the website is working.

Solution: The first thing to do is to create the instance in aws. In our case we will use a linux OS, specifically ubuntu .

When creating this service, a .pem key was created and thanks to it we are able to connect remotely to the aws instance.

```
ubuntu@ip-172-31-36-90:~$ ssh -i /home/heiko/.ssh/heiko_ubuntu_key.pem ubuntu@ec2-18-195-117-118.eu-central-1.compute.amazonaws.com
Welcome to Ubuntu 18.04.6 LTS (GNU/Linux 5.4.0-1084-aws x86_64)

 * Documentation:  https://help.ubuntu.com
 * Management:    https://landscape.canonical.com
 * Support:       https://ubuntu.com/advantage

System information as of Wed Sep 21 15:27:22 UTC 2022

System load: 0.01      Processes:            97
Usage of /:   24.4% of 7.57GB   Users logged in:     0
Memory usage: 23%      IP address for eth0: 172.31.36.90
Swap usage:   0%

35 updates can be applied immediately.
35 of these updates are standard security updates.
To see these additional updates run: apt list --upgradable

New release '20.04.5 LTS' available.
Run 'do-release-upgrade' to upgrade to it.

Last login: Wed Sep 21 15:24:21 2022 from 172.31.32.53
ubuntu@ip-172-31-36-90:~$
```

Later in another instance we installed ansible and configured all the files (mentioned in the practice "annotated-Infra-CB-S3-AO-W2-HW_v2") to the point of being able to execute commands or playbooks in the server that will host apache2.

```
ubuntu@ip-172-31-32-53:~/playbooks$ ansible all -m ping -i /etc/ansible/hosts --key-file '~/.ssh/heiko_ubuntu_key.pem'
server1 | SUCCESS => {
  "changed": false,
  "ping": "pong"
}
ubuntu@ip-172-31-32-53:~/playbooks$
```

Once the installation is ready, we start to create the playbook in the following way:

```
---
- name: Ansible Playbook to Install and Setup Apache on Ubuntu
  hosts: servers
  become: yes
  tasks:
    - name: Install latest version of Apache
      apt: name=apache2 update_cache=yes state=latest

    - name: Install latest version of libapache2-mod-wsgi-py3
      apt: name=libapache2-mod-wsgi-py3 update_cache=yes state=latest

    - name: Install latest version of python-dev
      apt: name=python-dev update_cache=yes state=latest

    - name: Install python3
      package:
        name: python3
        state: latest

    - name: install pip3
      apt: name=python3-pip state=present

    - name: Install flask python package
      ansible.builtin.pip:
        name: flask

    - name: Creates directory ExampleFlask inside ExampleFlask
      file:
        path: /home/ubuntu/ExampleFlask/ExampleFlask
        state: directory

    - name: generate __init__.py
      copy:
        content: ""
        dest: /home/ubuntu/ExampleFlask/ExampleFlask/__init__.py

    - name: Copy your my_flask_app.py file
      ansible.builtin.template:
        src: "~/my_flask_app.py"
        dest: "/home/ubuntu/ExampleFlask/ExampleFlask/"

    - name: Copy your my_flask_app.wsgi file
      ansible.builtin.template:
        src: "~/my_flask_app.wsgi"
        dest: "/home/ubuntu/ExampleFlask/ExampleFlask/"

    - name: Copy ExampleFlask.conf file
      ansible.builtin.template:
        src: "~/ExampleFlask.conf"
        dest: "/etc/apache2/sites-available/"

    - name: Enable the file with a2ensite
      shell: 'a2ensite ExampleFlask.conf'

    - name: Restart apache2
      shell: '/etc/init.d/apache2 restart'

    - name: Check connection (GET) to a page
      ansible.builtin.uri:
        url: http://172.31.36.90/testFlask/
```

Once the playbook has been created, we will configure the following files in the home/user directory

my_flask_app.py

```
ubuntu@ip-172-31-32-53:~$ cat my_flask_app.py
from flask import Flask
app = Flask(__name__)

@app.route("/")
def hello():
    return "Hello world!"
if __name__ == "__main__":
    app.run()
ubuntu@ip-172-31-32-53:~$
```

my_flask_app.wsgi

```
ubuntu@ip-172-31-32-53:~$ cat my_flask_app.wsgi
#!/usr/bin/python3.6

import logging
import sys
logging.basicConfig(stream=sys.stderr)
sys.path.insert(0, '/home/ubuntu/ExampleFlask/ExampleFlask')
from my_flask_app import app as application
application.secret_key = 'anything you wish'
ubuntu@ip-172-31-32-53:~$
```

ExampleFlask.conf

```
ubuntu@ip-172-31-32-53:~$ cat ExampleFlask.conf
<VirtualHost *:80>
    # Add machine's IP address (use ifconfig command)
    ServerName 172.31.36.90
    # Give an alias to to start your website url with
    WSGIScriptAlias /testFlask /home/ubuntu/ExampleFlask/ExampleFlask/my_flask_app.wsgi
    <Directory /home/ubuntu/ExampleFlask/ExampleFlask/>
        # set permissions as per apache2.conf file
        Options FollowSymLinks
        AllowOverride None
        Require all granted
    </Directory>
    ErrorLog ${APACHE_LOG_DIR}/error.log
    LogLevel warn
    CustomLog ${APACHE_LOG_DIR}/access.log combined
</VirtualHost>
ubuntu@ip-172-31-32-53:~$
```

Once the configuration files have been created, run the playbook as follows:

```

ubuntu@ip-172-31-32-53:~/playbooks$ sudo nano playbook1.yml
ubuntu@ip-172-31-32-53:~/playbooks$ ansible-playbook playbook1.yml --key-file '~/ssh/heiko_ubuntu_key.pem'

PLAY [Ansible Playbook to Install and Setup Apache on Ubuntu] *****
TASK [Gathering Facts] *****
ok: [server1]
TASK [Install latest version of Apache] *****
ok: [server1]
TASK [Install latest version of libapache2-mod-wsgi-py3] *****
ok: [server1]
TASK [Install latest version of python-dev] *****
ok: [server1]
TASK [Install python3] *****
ok: [server1]
TASK [install pip3] *****
ok: [server1]
TASK [Install flask python package] *****
ok: [server1]
TASK [Creates directory ExampleFlask inside ExampleFlask] *****
ok: [server1]
TASK [generate __init__.py] *****
ok: [server1]
TASK [Copy your my_flask_app.py file] *****
ok: [server1]
TASK [Copy your my_flask_app.wsgi file] *****
ok: [server1]
TASK [Copy ExampleFlask.conf file] *****
ok: [server1]
TASK [Enable the file with a2ensite] *****
changed: [server1]
TASK [Restart apache2] *****
changed: [server1]
TASK [Check connection (GET) to a page] *****
ok: [server1]

PLAY RECAP *****
server1 : ok=15  changed=2  unreachable=0  failed=0  skipped=0  rescued=0  ignored=0

ubuntu@ip-172-31-32-53:~/playbooks$

```

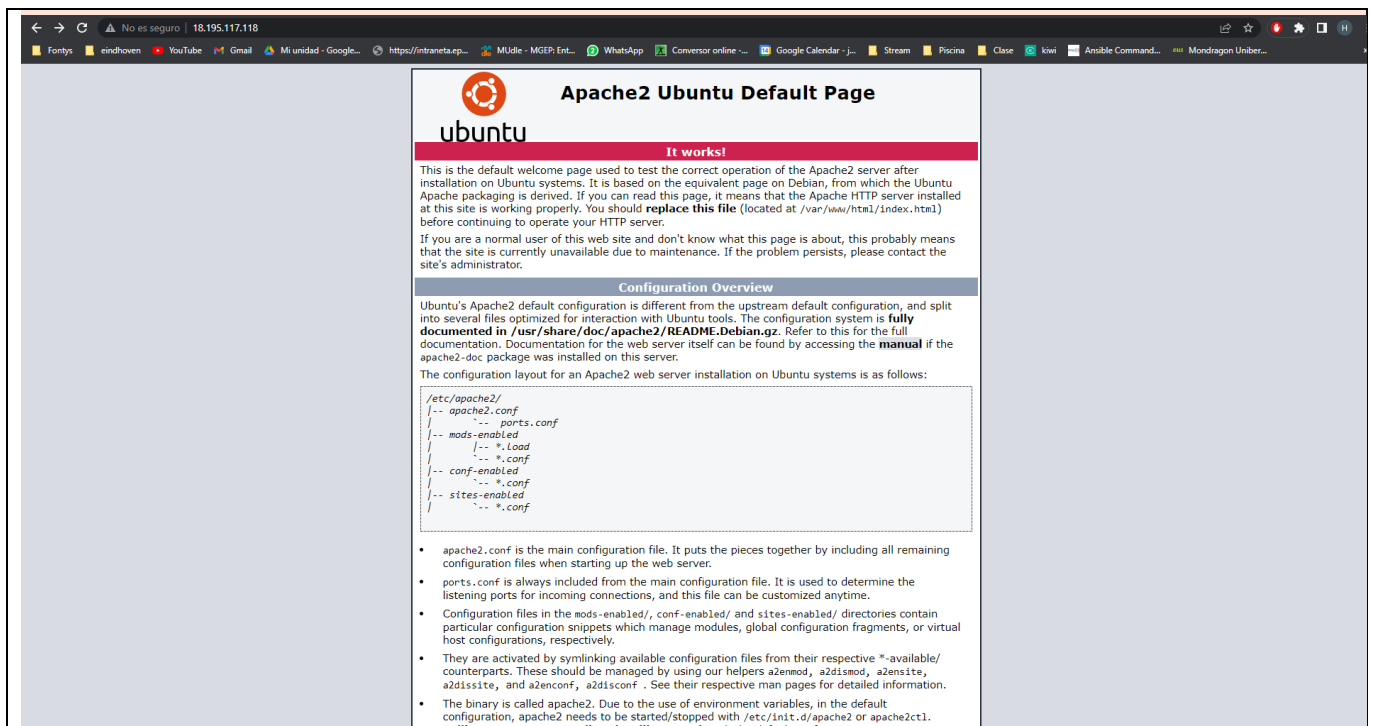

As we can see in the image the playbook is able to install and configure everything needed to run apache correctly and securely, as you can see in the last image the page returns a status of 200 (ok).

```

TASK [Check connection (GET) to a page] ***
ok: [server1]

```

On the other hand, if we connect via the browser, we will see that the Apache is working correctly even if it does not have any web page.

Finally, in the case of using a wget from another instance to the machine, we can observe that it downloads the page correctly if we use the following URL:

```
ubuntu@ip-172-31-32-53:~/playbooks$ wget 172.31.36.90/testFlask/
--2022-09-21 15:21:33-- http://172.31.36.90/testFlask/
Connecting to 172.31.36.90:80... connected.
HTTP request sent, awaiting response... 200 OK
Length: 12 [text/html]
Saving to: 'index.html'

index.html                               100%[=====] 12 --.-KB/s  in 0s

2022-09-21 15:21:33 (1.85 MB/s) - 'index.html' saved [12/12]

ubuntu@ip-172-31-32-53:~/playbooks$ cat index.html
Hello world!ubuntu@ip-172-31-32-53:~/playbooks$
```

We see how the page returns a "hello world!" as in the example provided.
